

## Lua in the NetBSD Kernel

Marc Balmer <[mbalmer@NetBSD.org](mailto:mbalmer@NetBSD.org)>

# Topics

## ① The Programming Language Lua

- The Lua Interpreter
- Syntax and such
- Modules

## ② Embedding Lua in C Programs

- State Manipulation
- Calling C from Lua
- Calling Lua from C

## ③ Lua in the NetBSD Kernel

- Use Cases
- Implementation Overview
- Implementation Details

## Running Lua Sourcecode

## Compiling / Running Lua Bytecode

## Running from C

- `int luaL_dofile(lua_State *L, const char *filename)`
- `int luaL_dostring(lua_State *L, const char *str)`

# Values, Variables, and, Data Types

- Variables have no type
- Values do have a type
- Functions are first-class values

# Tables

- Tables are THE data structure in Lua
- Nice constructor syntax
- Tables make Lua a good DDL
- Metatables can be associated with every object

# Lua Table Constructor

Create and initialize a table, access a field:

```
mytable = {  
    name = 'Marc',  
    surname = 'Balmer',  
    email = 'm@x.org'  
}  
  
print(mytable.email)
```

# Extending Lua Programs

## Access GPIO pins from Lua:

```
require 'gpio'  
  
g = gpio.open('/dev/gpio0')  
g:write(4, gpio.PIN_HIGH)  
g:close()
```

## Creating and Destroying a State

- `lua_State *L = lua_newstate()`
- `luaopen_module(L)`
- `lua_close(L)`

## Calling a C Function

- Function has been registered in `luaopen_module()`
- `int function(lua_State *L)`
- Parameters popped from the stack
- Return values pushed on the stack
- Return Nr. of return values

## Calling a Lua Function

- Find the function and make sure it is *\*is\** a function
- Push parameters on the stack
- Use `lua_call(lua_State *L, int index)`
- or `lua_pcall(lua_State *L, int index)`
- Pop return values from the stack

# Calling a Lua Function

## The Lua function

```
function hello()  
    print('Hello, world!')  
end
```

## Call hello from C:

```
lua_getglobal(L, "hallo");  
lua_pcall(L, 0, 0, 0);
```

## Ideas for Users

- Modifying software written in C is hard for users
- Give users the power to modify and extend the system
- Let users explore the system in an easy way

## Ideas for Developers

- „Rapid Application Development” approach to driver development
- Modifying the system behaviour
- Configuration of kernel subsystems

# Alternatives

- Python
- Java

# Python

- Not too difficult to integrate in C
- Huge library
- Memory consumption
- Difficult object mapping

# Java

- Easy to integrate
- Difficult object mapping
- Memory considerations
- Has been used for driver development

## Lua in NetBSD Userland

- Library (liblua.so) and binaries (lua, luac) committed to -current
- Will be part of NetBSD 6
- No back port to NetBSD 5 stable planned

## Lua in the NetBSD Kernel

- Started as GSoC project, porting Lunatik from Linux to NetBSD
- Proof that the Lua VM can run in the kernel, lack of infrastructure
- Infrastructure beeing added now

## Running in Userland

- Every process has its own address space
- Lua states in different processes are isolated

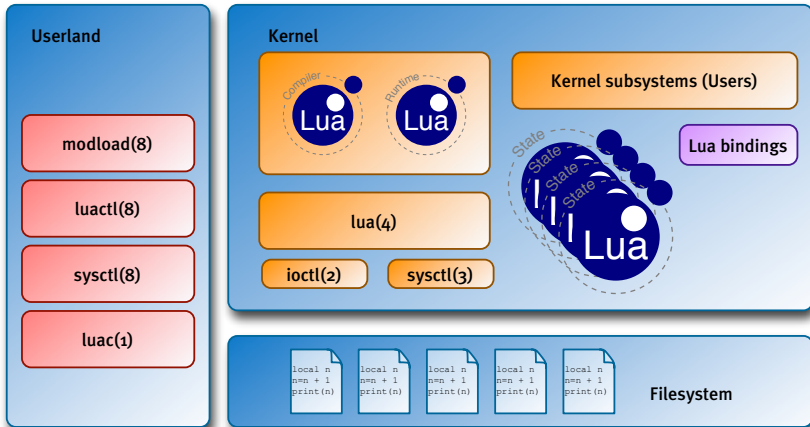

# Running in the Kernel

- One address space
- Every thread that „is in the kernel“ uses the same memory
- Locking is an issue

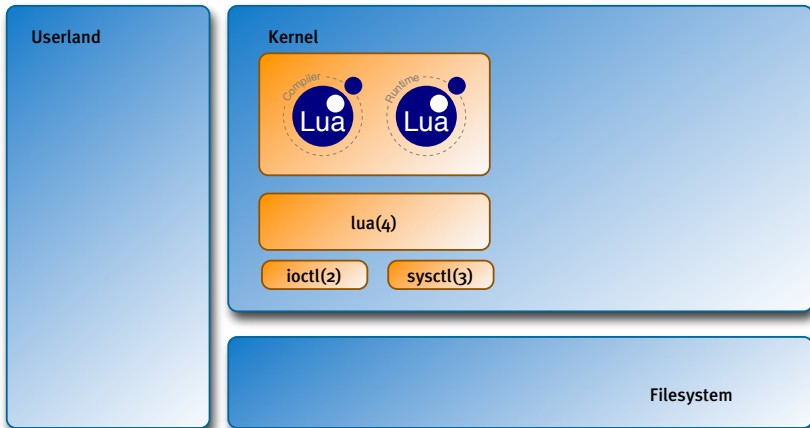

# The Big Picture

# The lua(4) Device Driver

# lua(4) ioctl(2) / sysctl(3) Interface

# Lua States

Userland

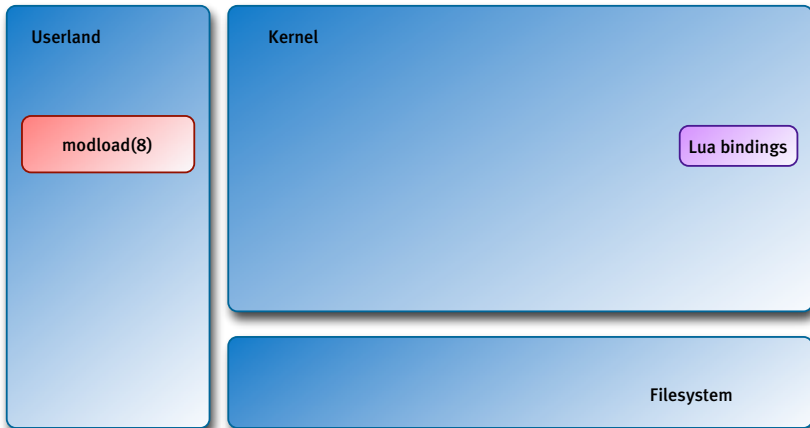

Kernel

Filesystem

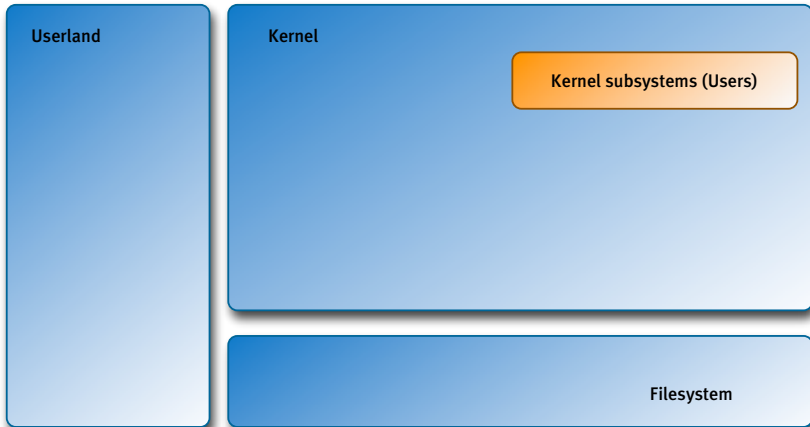

# Lua Modules

# Lua Users

# The luactl(8) Command

## „require”

- Modules are kernel modules
- 'require' can be turned off
- Modules must be assigned to Lua states by hand then
- By default 'require' is on and modules are even autoloaded
- Module autoloading can be turned off

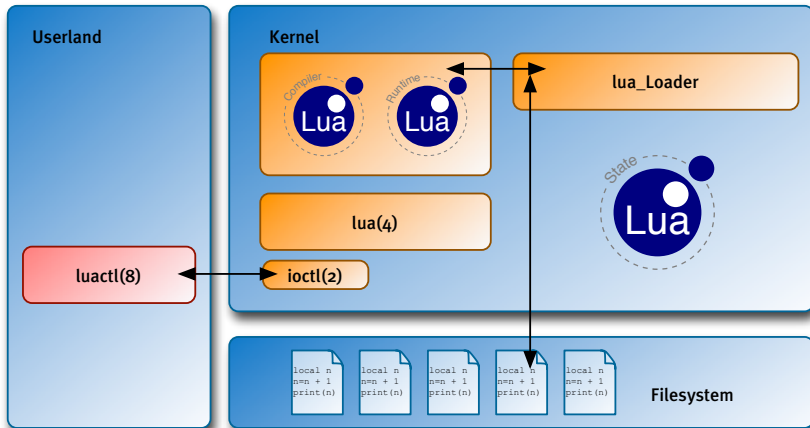

## sysctl(8) Variables

- kern.lua.require=1
- kern.lua.autoload=1
- kern.lua.bytecode=0
- kern.lua.maxcount=0

# Loading Lua Code

# Security

- New Lua states are created empty
- Full control over the loading of code
- No access to kernel memory, -functions but through predefined bindings

# Time for Questions
